Abstract

Recently debates have emerged concerning how atmospheric objects referred to collectively as ‘elemental’ become entangled in the operation of communication infrastructure. The paper extends these debates through research into UK emergency responders’ information sharing during emergencies. Harnessing textual analysis and an interview, the paper unpacks the protocols established to organise information sharing and explores how such protocols interweave an assemblage of technologies to share information as emergencies unfold. The evidence presented demonstrates different ways that the elemental forces physically constitutive of emergencies are incorporated into information sharing. However, it also details cases wherein these elemental forces disrupt the information sharing practices they otherwise enable and outlines the effects this disruption has on emergency response provision. Considering the case, I make three arguments to establish a distinctive approach for conceptualising the entanglement of the elements within information sharing. Firstly, I extend understandings of the capacities that elements actualise to enable information sharing. Secondly, I elaborate upon the notion of excess to explain how elemental forces disrupt information sharing. Accounting for its political ramifications, I demonstrate thirdly, how, by disrupting information sharing, elemental forces obstruct government capabilities to comprehend the emergencies they attend and, in turn, provide resources to ensure adequate response.

**Keywords**: emergency, communication, elemental, atmosphere, infrastructure, governance
Geographies of Information Sharing and the Elemental

In this paper, I explore the practices through which UK authorities share information during emergencies. I pay particular attention to the procedures and protocols developed to arrange information sharing. Furthermore, I probe how such protocols formalise the use of an assemblage of technologies which facilitate the movement of information across space. By generating information concerning the events being responded to, these practices shape the actions that authorities undertake to govern emergencies amidst their unfolding.

Underlying the empirical case of the paper are important connections to broader debates in geography concerning how to conceptualise the material basis of information sharing. On first appearance, geography’s engagement with the practices by which information is shared across space appear counter-intuitive to our everyday experience of them. Rather than being dressed up as immaterial or disembodied, literature has demonstrated how information sharing is grounded in, and reliant upon, an array of material objects (see for instance, Dodge and Kitchin, 2011, Kinsley, 2013, Leszczynski, 2015). This materialist approach is reflected by research, for example, into internet cables deep within the world’s oceans (Starosielski, 2015) or the hardware that sits on workstations across the world (Batty, 2013, Neyland, 2015, Graham et al, 2017). Other work has concentrated on the material spaces created to manage data produced; including storage facilities furrowed hundreds of metres below the world’s surface (Graham, 2016). Similarly important has been research that explores how technologies evoke affectively perceived states shared with and across human bodies. In relation to gaming, for example, James Ash has excavated the

1 For Starosielski, this everyday experience extends to academic domains too. She states that ‘Analyses of twenty-first century media culture have been characterised by a cultural imagination of dematerialization: immaterial informational flows appear to make the environments through fluid and matter less’ (2015, 6).
‘interface envelopes’ (15, 2015) made and remade at the intersection between computer screens, human users and the wider material space in which these relations are performed. Amongst these debates is an emergent trajectory that considers the entanglement of elemental forces within the operation of these material devices. Similar to how geography more generally has understood them², this research has taken ‘the elemental’ largely in their pre-Socratic, Empedoclean incarnation (1995), referring to how air, earth, water and fire in different forms encounter media technologies. Air has been considered in different guises by its envelopment within information sharing technologies dating back, in some cases, hundreds of years (Amoore, 2016, McCormack, 2016, Peters-Durham, 2001, 2015). Alternately, Nicole Starosielski has investigated how water and earth, in the form of oceans and sea beds, play important roles in the functioning of internet infrastructure (2015). Furthermore, Jussi Parikka (2014, 2015) and Sean Cubbit (2016) have explored how smartphones rely on the degradation of finitely available resources such as lithium and aluminium.

Important for this paper is how this literature has begun to document the various, productive roles that elements play in information sharing. That is, how the elements are harnessed and afforded functions in facilitating information sharing. Probing what he calls elemental infrastructures, Derek McCormack expands on the ‘literal’ (2016, 6) role that elements contribute to information sharing. Here, the elements are considered in terms of how their physical force enables information sharing. Thus, McCormack explores how air currents make possible the functioning of experimental balloon technologies that might

²Geographical literature on the elements is substantial (Clarke 2007, Whatmore 2006, Yusoff 2015), so much so that the literature reviewed in this article concentrates exclusively on elements within information sharing.
change global access to the internet. This literal role exists alongside a ‘metaphorical’ (2016, 2) one for McCormack, where the allusion to the elements are pivotal in helping users and designers of technologies to conceptualise at an abstracted level the material and cognitive processes through which information sharing is brought to bear. McCormack references Louise Amoore’s work on cloud computing as exemplary of the metaphorical role of the elements. Summarising this role, Amoore claims that ‘the cloud in cloud computing is widely held to derive from the mapping of infrastructures of computer networks, where the visualisation of a figurative cloud stands in for the complexity of the internet’ (Amoore, 2016, 2, my emphasis). Amoore shows how, in terms of the imaginaries that surround them, elements are leaned on to enable thinking through the generation of information and its transmission across circuits. This metaphorical role resonates with a broader corpus of literature that probes the representational role elements adopt to facilitate information sharing (Edwards, 2010, Peters-Durham, 2001, 2015). Paul Edwards, for example, has inquired into the range of mechanisms through which physical weather fronts take on a second life on computer and television screens. Offering a historical account, Mary Favret (2009) has described how, in previous eras, a nation’s populace kept abreast with the development of wars abroad through newspaper reports that not only enumerated fallen soldiers and territorial gains but also evoked the atmospheric conditions that shrouded the battlefield. Considered through the nomenclature of representation, then, is how information acts as an interlocutor for the physical state of the elements that it reflects despite being detached from.

As McCormack astutely notes, identified and probed across this literature are the range of capacities that elements perform when enrolled into information sharing practices (Bryant, 2011, De Landa 2006, Feigenbaum, 2014, Peters, 2010, Whatmore, 2006). As Manuel De
Landa (2002) has shown, capacity structures inquiry into objects in specific ways. Rather than making normative claims concerning the properties inherent to objects, capacity emphasises what an object might do and the roles that it can perform. Capacity, then, emphasises examination of an object’s potential rather than focusing on how the actions it performs may be the result of its supposed nature. This focus on potentiality means an object’s capacity is actualised contingent upon the relations it makes to other things and the practices in which it becomes enveloped. The notion of capacity does not direct attention to that which is apparently internal to the elements. What matters instead is how the elements act according to the relations they make and the process-inflected circumstances they become enrolled within (See also McCormack, 2017, 2014). Rather than concentrating on what elements supposedly are, capacity draws focus to what such elements might do when entangled in particular practices.

This rendition of capacity provides an important segue to explaining why I discuss elements as ‘forces’ in this paper. If capacity emphasises what elements do according to the circumstances in which they are situated, force orients investigation towards the influence and affect elements have within these circumstances. In other words, whereas capacity accounts for the roles that elements play, force addresses the impact elements bring about when performing these roles. Elaborating on what he describes as ‘the force of the elemental’ (2015, 54), Pete Adey probes the tension between the elements and human capabilities to comprehend them. For Adey, we should understand ‘elements as anterior to human perception’ (2015, 55) and possessive of agency beyond our intelligibility.

Nevertheless, the force of the elemental is felt in the myriad ways that elements shape and nudge the circumstances in which they are present. Adey shows how elemental force is present, albeit implicitly, in geographical literature ranging from explorations of how the
climate influences peoples’ decisions about where in cities to live to Andrew Barry’s work on how air quality shapes the development of technological fields related to pollution governance. In his recent work, Pete Forman (2017) develops conceptualisations of elemental force further through research into the securing of gas pipelines. For Forman, elemental force is traceable in the modes of mobility that elements exhibit within the broader material processes in which they are incorporated. Echoing Jane Bennett’s observations regarding the recalcitrance of material objects (2010), Forman argues that force is embodied by the capacity of elements to cause friction within the processes of which they are part. As much as it refers to the formative influence elements have, force also encapsulates the ability of elements to resist and disrupt the processes in which they are enveloped.

Along with providing a basis for investigating precisely how, and with what kinds of capacity, they contribute, an emphasis on force opens up to consideration the disruptive reverberations elements might instigate within information sharing practices. In literature up to this point, the disruption that elements cause to information sharing has received scant attention. Returning to her work, Favret discusses delays in the transmission of information. However, Favret understands these delays as caused not by the force of the elemental but by the speed at which technologies themselves can operate to move information across distance. As the empirical locus of attention in this paper, emergencies certainly provide a provocative site in which to initiate explorations of the disruptive force of the elemental in information sharing³. Although elemental forces themselves have not

³Indeed, the disruptive force of the elemental has been mentioned in passing before. Part of an investigation into the New Orleans Police Department’s response to Hurricane Katrina, Benjamin Sims (2010) describes how the Hurricane damaged radio antennas and how the storm effected local electricity supplies so that walkie-
heretofore been seriously considered as a contributing factor, emergencies are continually characterised in literature by their contingency and indeterminacy. Emergencies are said to rupture various interwoven constituents of social order, including the norms and routines that make up daily life (Anderson, 2011, Opitz and Tellman, 2015 Rodrigues-Giralt et al., 2014). Emergencies lay bare the fragilities embedded in material infrastructure (Collier et al., 2017, Lakoff and Collier 2010). In sites such as emergency control rooms that continually monitor for their potential occurrence, the ever-acknowledged imminence of emergencies blurs the line between an event happening and not happening (Anderson and Gordon, 2016). Especially relevant for this paper, the disruptive character of emergencies is integral to readings of the politics that emanates from them. This is particularly the case when considering the forms of intervention taken by authorities to govern emergencies. Work that has investigated techniques for preparing for future emergencies stress, for instance, the importance of the uncertainty that surrounds future emergencies in legitimating actions that governments take in the present (Amoore, 2013, Aradau and Van Munster, 2011, de Goede, 2012). Alternately, Ben Anderson (2015) has discussed the strange status of emergencies as events that challenge the ability of authorities to know and to label amidst their unfolding whilst simultaneously activating the need for response in line with the state’s promise to come to the aid of populations in times of crisis. Whilst Marieke de Goede (2014) has shown how state inactivity before and during emergencies can reconstitute relations between the public and respondent authorities.

talkies and personal mobile phones could not work either. Challenging authorities’ capability to communicate across the disparate sites of the emergency, the literal force of the elements had a very serious impact on the technologies utilised by emergency responders, making coordination between agencies extremely difficult and playing a decisive role in determining whether lives could be saved or not.
Pre-existing literature orients the paper towards considering both the facilitative and disruptive effects elements manifest in emergency information sharing. By their perceived indeterminacy, furthermore, emergencies open up to inquiry the political ramifications that rise to prominence where elemental forces become enveloped in information sharing. Pursuing these lines of inquiry, the paper moves from this introduction through four sections before its conclusion. In the first of these sections, I introduce in more depth the empirical case study of the paper by contextualising the information sharing procedures and technologies through which emergency responders communicate during emergencies. Secondly, I expand upon the capacities elements actualise in contributing to emergency information sharing. Thirdly, I provide evidence for and conceptualise anew the ways in which elemental forces disrupt information sharing. Fourthly, I detail the political ramifications that elemental disruption has by describing how it compromises authorities’ capability to both understand and render governable emergency events as they unfold. In the conclusion, I both summarise the paper’s observations and reflect on its broader implications for the attention geography pays to moments where information sharing and the elemental meet.

**Coordination, Multi-Agency Incidents and Information Sharing**

Over the last decade, the issue of how different authorities coordinate response to emergencies has become a pressing issue for the UK government. The importance of coordination has been reflected in academic debates concerning emergency response in recent times, with research focusing on preparatory practices instigated in lieu of the 2004 Civil Contingencies Act (Adey and Anderson, 2011, 2012), the development of new legislative bonds between emergency responders (Zebrowski, 2015) and the enrolment of
non-security related organisations into emergency preparedness (Coaffee, 2010, Grove, 2014). Research has yet to consider, however, how this need for better coordination has led to the creation of new arrangements by which authorities share information with one another during emergencies. Such arrangements have been designed specifically to aid coordination when attending to what are commonly referred to as ‘multi-agency incidents’ (2011, 2016, 2017). Multi-agency incidents account for emergencies, be they for instance floods, fires or snowstorms, which bear specific spatial and temporal characteristics. They are emergencies that are widespread, taking place across multiple sites simultaneously. Owing to their disparate spatiality, they can also have a diverse range of impacts on human life, environments and infrastructure (2016). In 2012, the U.K government established the Joint Emergency Services Interoperability Programme (JESIP) to develop new arrangements so that different authorities involved in emergency response, from the Police to Fire and Rescue Services, Ambulance Services and the Environment Agency, can cooperate when planning for and responding to multi-agency incidents. Although established nationally through JESIP, local authorities tailor these arrangements to make them suitable for the risks prevalent in their area.

Under JESIP, authorities have acquired and developed various technologies to generate and circulate information during emergencies⁴. This includes cloud-based data storage and sharing platforms, emergency transmitters and multi-line telecommunication facilities. Equally as important, new information sharing procedures have been crafted in tow with these technologies. Authorities have designed new warning systems, protocols for reporting

⁴Additional efforts have been made, for instance, to train different authorities to assess risks in similar ways to one another, to increase awareness amongst authorities of each other’s strategic priorities and to develop planning procedures that are the result of collaboration (2016).
from emergency sites, expert advice conduits and information sourcing and compilation guidelines. These procedures are brought together to structure the deployment of technologies so that information can be sourced and circulated as emergencies unfold. Much of the information shared concerns the elemental forces and conditions physically constitutive of emergencies. From the examples in this paper, information might be generated regarding ground water swell in floods, snowfall in winter storms, smoke produced by fires or weather patterns precipitating emergencies. Authorities also share strategical information to coordinate their response to emergencies. This includes, for example, information relating to resources deployed and how different authorities should divide the labour of response amongst themselves.

The empirical material presented in this paper derives from research that interrogated how the design of procedures and use of technologies enable formalised and routine information sharing to take place between authorities during emergencies. Six months textual analysis was undertaken that involved identifying and reviewing the content of both guidelines stipulating how technologies should be procedurally deployed and reports that reflect on the success of information sharing in the aftermath of specific emergencies. Furthermore, the paper draws on an interview conducted with the Chief Emergency Planner of a Local Resilience Forum (LRF). LRFs bring local emergency response authorities together so they can collectively prepare for emergencies. Elaborating on themes identified through textual analysis, the interview focused on information sharing procedures and technologies, examples of their use in past emergencies and the evaluation that authorities make concerning the effectiveness of emergency information sharing practices. The empirical material generated demonstrated that elemental forces constitutive of emergencies play a pivotal and varied role in the operation of information sharing practices. At the same time,
the material also revealed how elemental forces disrupt information sharing. The paper now turns to present this empirical material and elaborate on its significance for debates concerning the relationship between the elements and information sharing.

**Actualising elemental capacities in emergency information sharing**

In this section I demonstrate how, to make information sharing possible during emergencies, procedures and technologies actualise both the physical and representational capacities of the elements. Although identified in extant literature (Amoore, 2016, Edwards, 2010, McCormack, 2016), the paper extends conceptualisations of these capacities by elaborating upon the relations that exist between them. Returning to his work, Pete Adey argues that to understand ‘the relationship between representation and process’ (2015, 56) that elements are caught up in, one has to ‘work back from the air, skies, clouds and how they are perceived and represented … to consider, for instance, the particular meteorological conditions that might have inspired Turner’s diffused and atmospheric scenes’ (ibid). Here, Adey implies that the physical force of the elemental plays a crucial role in determining their capacity to be represented. Extending Adey’s observation, I detail in this section how procedures and technologies facilitate information sharing by establishing lines of relation between the representational and physical capacities of elemental forces. Rather than existing separately, the physical and representational capacities of the elemental are mutually cultivated through the enactment of information sharing practices. Mutual cultivation is evidenced by how information sharing procedures attune with the spatial and temporal unravelling of the physical force of the elements constitutive of emergencies. In other words, through procedures, the physical force of the elemental is made to dictate when, and across what sites, information sharing should be enacted. This
attunement, in turn, allows the technologies procedurally deployed to source and circulate information representative of the elemental forces underpinning emergencies.

For emergency responders, the elements commonly first appear in their representational capacity through the array of data flows, technologies and arrangements used to warn authorities of potential emergencies. The key warning software in the UK is the National Weather Warning Service. Designed and supplied by the Met Office, the service provides continual updates concerning shifts and trends in weather patterns surrounding the UK. These updates include assessments of weather patterns on two fronts: the likelihood that they will lead to emergencies and the potential impact an emergency might have. Likelihood refers to the statistical probability that a weather pattern will continue to move and encroach upon a specific area, thus bringing about the event that it potentially possesses. Impact, alternately, accounts for the effects that the emergency might have on infrastructure, environments and life and the extent of these effects.

These warnings are mobilised as a temporally routinized procedure for authorities. As the emergency planner explained; ‘At two o’clock’ …‘We all (emergency responders) get automated ones’ (my brackets), related to conditions such as ‘flooding, wind excetra’\(^5\). Visualised on a map of the region, these warnings are colour-coded. In relation to imminent emergencies, two colours are of interest: yellow and amber\(^6\). Whereas yellow suggests the

\(^5\)All subsequent quotes generated from my interview with emergency planner 03/02/2017

\(^6\)Two further colours might appear on a National Weather Warning Service update: green and red. Green will appear when no potential for severe weather exists. Red will appear when areas are in the midst of a severe weather pattern.
need to remain aware of continuing developments in the weather, amber will initiate action from emergency responders.

Representative of the elemental forces that collectively constitute weather fronts, warnings operate as thresholds that, when breached, instigate the physical extension of new information sharing conduits across space. Action will be taken according to the emergency planner; ‘definitely when there’s an amber, possibly if there’s a yellow…and if anybody says actually we think this requires some multi-agency coordination, police will call… a Response Working Group’. Connecting the upper echelons of the local Police, Fire and Rescue Service, Ambulance Services, the Environment Agency and local government, Response Working Groups (RWGs) are initially formed virtually using a secured, multi-line telecommunications system. Each member of the group is charged with sourcing information regarding aspects of the emergency for which they are responsible. Whereas the Fire and Rescue Service would collect information concerning challenges for the evacuation of communities, for example, the Environment Agency might gather information pertaining to the potential adulteration of water supplies.

To generate information representative of them, lines of communication attune spatially with the physical unfolding of elemental forces constitutive of emergencies. Members of the RWG thus establish connections with the possibly multiple sites across which the emergency is physically taking place. What are called Liaison Officers are sent to the sites affected by the emergency to gather information and feed it back to the RWG (2013). In flood emergencies, for instance, procedure dictates that members of the RWG make connections

\[\text{\textsuperscript{7}}\text{See figure one.}\]
with the sites at which water levels are highest. Simultaneous with the spatial extension of information conduits to the sites of the emergency, various ‘cells’ will be created. Cells are clusters of experts who advise on issues that arise according to the emergency responded to. One such cell is the Scientific and Technical Advisory Cell (STAC). The STAC provide respondent authorities with guidance on matters ‘such as the impact on the health of the population, public safety, environmental protection’ (2007, 2). Individual members of the STAC will coordinate with one another to supply ‘valuable information and arrive at a common view of the scientific and technical merits of different courses of action’ (2007, 3) that authorities might pursue. Encapsulating another way in which the physical capacities of the elemental forces underpinning emergencies shape the enactment of information sharing procedures, cells are formed in a way sensitive to the specific demands of different emergencies. ‘The composition of and functioning of the STAC’ (2007, 3), guidelines dictate, ‘will be incident specific and tailored to local requirements’ (ibid). This sensitivity is evident when considering the involvement of different experts in a cell. As guidance states, ‘As an incident progresses, the focus may move away from health matters to, for example, wider environmental concerns. It may therefore be appropriate for the lead to be reassigned to a more appropriate person with the necessary knowledge and experience’ (2007, 4). Building

---

8STAC cells were established in the wake of the Buncefield Oil Depot Explosion in 2005 which ‘highlighted weaknesses in arrangements for providing coordinated scientific and technical advice’ (2007, 1).

9The agencies potentially involved in a STAC are varied, crossing the public and private divide. Companies operating infrastructure ‘will be responsible for providing timely and accurate information’ (ibid) regarding risks faced should an emergency affect their services. The Food Standards Agency might report on the damage to food supplies or limits to its availability whilst various organisations will be called upon to advise on animal welfare. In incidents involving chemical, biological, radiological and nuclear material’ (2007, 9), Ministry of Defence experts provide ‘advice on handling any device as well as identifying and advising on the material involved and appropriate counter-measures that might be taken during initial response’ (ibid). In this event, the Government Decontamination Service would provide ‘advice and guidance on decontamination of buildings, infrastructure, mobile transport assets and the open environment’ (ibid).
on the distribution of Liaison Officers, cells are fluid entities, the occupants of which, and information generated therein, are subject to continual reassembly in a way that mirrors and incorporates the physical force of the elements constituting the emergency itself.

With the formation of RWGs, Liaison Officers and cells, a spatial network develops reflective of the physical unfolding of elemental forces underpinning the emergency to generate information representative of it. Information is transmitted from the sites within this network to establish an overall understanding of the emergency. Containing information ‘on the nature and scale of the emergency’ (2014, 23) as calculated from specific sites, information is circulated across this network though a procedure known as situation reporting (SITREPs). SITREPs report on the geographical coordinates of the locations and aspects of local infrastructure affected whilst simultaneously operating as a risk assessment of what might be to come. They also report on the strategic actions taken to attend to the emergency, the agencies present at different sites and the resources deployed. Adding to the material technologies present, SITREPs are transported to Response Working Groups via Resilience Direct, a cloud-based platform that responders access via a regular internet connection. Concurring with Amoore’s (2016) observations about cloud-based intelligence sharing devices, the circulation of information through Resilience Direct instantiates a range of new possibilities for authorities in perceiving the object of governance. Receiving information through Resilience Direct, the RWG collates all the information fed to it and integrates it to form a Common Received Information Picture (CRIP). Sent to all sites where response is taking place, CRIPs offer a representative overview of the latest developments that characterise the physical unfolding of the emergency. Taking me through the CRIP template they use, the emergency planner demonstrated the various forms of information
that a CRIP possesses\textsuperscript{10}. Along with information regarding how the local and national media are reporting the emergency’s development, CRIPs contain information relating to the emergency structured by the METHANE acronym. Going through each letter of this acronym, CRIPs will first indicate whether authorities have declared a ‘Major incident’. Using Ordinance Survey coordinates, CRIPs then detail the ‘Exact locations’ that the emergency has effected before turning to describe the ‘Type of Incident’ occurring and what ‘Hazards’ are present. The CRIP will then outline the best ‘Access’ routes for emergency responders to take when arriving at different scenes, the ‘Number of Casualties’ that the emergency has caused and the ‘Emergency Services’ currently in action or required. For example, and revealing the centrality of the representation of the elements, a CRIP circulated during major flooding in 2014 explained how ‘due to East Coast Surge, groundwater … reached some of its highest levels\textsuperscript{11}, leading to ‘coastal flooding’ (ibid) which was ‘impacted on by the direction of the wind (which) became south-westerly’ (ibid). The CRIP reports that with ‘103 properties flooded, landslip continues causing some issues, 44,000 people suffering power outages’\textsuperscript{12}. Because of ‘the river eroding the road’ a ‘multi agency team will be on site to assess and take action…first water management solution, dams and temporary storage will be completed tonight.. water rising and will need (Local County Council) support. Road issues at… will need water management solution, which is beyond capacity of the military’\textsuperscript{13}.

\textsuperscript{10}For the emergency planner, CRIPs account for ‘what command structures are up and running, what’s happening and what actions are they (authorities) undertaking’.

\textsuperscript{11}TCG Debrief Minutes from 10/06/2014

\textsuperscript{12}Situation Report from 15/02/2014

\textsuperscript{13}Situation Report from 19/02/2014
With procedures locating information sourcing technologies at the scene, the information contained in CRIPs is also able to change in a way attuned to, and representative of, the real time unfolding of the emergency and the elemental forces that physically underpin it. A term borrowed from the military, adjustments to the information contained in CRIPs occur according to a ‘battle rhythm’, a pre-determined structure that states when information should be released. At the first signs of an emergency, the RWG will ask ‘what’s the battle rhythm?’ amongst its members. The emergency planner continued to offer a hypothetical scenario of the instructions through which they construct a battle rhythm. Addressing the Liaison Officers and Cells responsible for SITREPs, the RWG might state that ‘we’re going to be asking for your up to date stuff at half eight’. This would mean that ‘we (RWG) can provide it (a CRIP)... at 9 o’clock’. Then, referring to SITREPs received from Liaison Officers and Cells: ‘they’ll feedback at half nine so we’ll (RWG) want our next meeting at ten so can do our actions (start compiling a new CRIP from SITREPs received)’\textsuperscript{14}. Through the creation of a battle rhythm, information is circulated according to a pre-conceived temporal skeleton that is mutually coordinated between the disparate spaces across which the emergency is physically present, emergency response is arranged and, consequently, information sharing procedures and technologies extend.

Organised by procedures, an array of technologies and agencies work to generate and circulate information that allows authorities to maintain a continual overview of the emergency. But how does the enactment of these practices extend our understanding of the physical and representative capacities that elemental forces actualise in information

\textsuperscript{14}My brackets
sharing? In line with the emphasis that the notion of capacity places on relations, the practices described suggest that the physical and representative capacities of elemental forces do not exist separate from one another. Instead, procedures and technologies operate to mutually cultivate these capacities to enable emergency information sharing. Procedures and technologies are deployed in a way that spatially and temporally mirrors and stays with the physical unfolding of the elemental forces underpinning emergencies. This roll out, in turn, allows for the generation of real-time information representative of the emergency.

‘You’d always be behind wouldn’t you?’ Elemental Excess in Information Sharing

For the emergency planner interviewed, the spatial and temporal manoeuvres by which the physical and representative capacities of elemental forces are mutually cultivated are not the only relations that exist between information sharing practices and the elements in emergencies. When in the midst of an emergency, the planner claimed that ‘you’d always be behind wouldn’t you?’ Expanding on their rhetorical question, they stated that, although one might implement measures designed to keep up-to-date with it, information sharing practices are always steps behind the physical unfolding of the emergency.

The emergency planner’s concerns imply that the disruptive force of the elemental outlined earlier (Adey, 2015, Forman, 2017) is present within emergency information sharing. But how might the type of disruption pertaining to information sharing be conceptualised? This section details specifically how the force of the elemental in emergencies exceeds practices designed to generate and circulate information representative of it. The notion of excess is

15 Interview with Emergency Planner 03/02/2017
heretofore unexplored in relation to the force of the elemental and its effects on emergency
governance. Nevertheless, excess has pre-existing gravitas in geographical debates seeking
to address the dynamism of objects in general. Ben Anderson and John Wylie (2009) raise
two important points regarding excess. Firstly, excess articulates an object’s life beyond its
capture as a device of human intention. Under this rendition, an object might be thought of
as ‘perpetually beyond itself’ (2009, 332) and transgressive of our regimented mobilisation
of it. Secondly, excess is closely tied to the virtual because it shows that ‘the actualisation of
matter is an eliminative manoeuvre that holds the explosiveness of an excess in check’
(2009, 329). In other words, objects possess the potential to exist in ways beyond how they
are materialised at any one point. To think of them through excess is to think objects as
‘rendered groundless by a more to come’ (2009, 331) that ever remains on the horizon.

Taking lead from Anderson and Wylie’s provocations, I develop and elaborate the notion of
excess in new ways to explain how the elements disrupt emergency information sharing. In
what follows, such a novel expansion of excess is offered in two ways. I have noted
throughout the paper that the capacities of elements are contingent on the relations they
forge. Continuing this line of thinking, the paper shows first how authorities’ failure to enact
information sharing procedures means that information potentially available concerning the
elements constituting emergencies is not captured and circulated. Here, the capacity for

16Tom Lundburg and Nick Vaughn-Williams use the term excess to encapsulate the often turbulent dynamic by
which practices of infrastructure protection are deployed. However, the authors’ focus here is different from
the aims pursued in this paper. Firstly, the authors opt for a broad conceptualisation of ‘life’ as encompassing
all manner of living entities. Such a focus is different from this paper’s aim to conceptualise the elements in
both their actualisation of capacities and force. Secondly, the authors are interested in how the excess of ‘life’
affects governing practices. Excess is presumed here and assessed via the traces it leaves behind in shaping
faltering critical infrastructure protection practices. In this paper, I am interested in how elemental excess is
produced and then how it turns to effect capabilities to both know emergencies and render them governable.
Elemental excess is actualised not by the elements in and of themselves but by the misapplication of information sharing procedures with which they are entangled. Secondly, I also outlined earlier how inquiry into the force of the elemental opens up to consideration the recalcitrant capacities that elements possess. Expanding this insight, I show how the potential for elemental forces to physically transform and impact upon circumstances in ways that authorities have not anticipated means that procedures and technologies can neither attune with their physical capacity nor generate information representative of them. Here, the unpredictable mutability of elemental forces brings about forms of excess to disrupt information sharing.

Elemental excess, then, is first produced by authorities’ lapses whilst attempting to follow their own procedures. In emergencies that necessitate multi-agency response, the set of information sharing procedures implemented are supposed to enable the smooth circulation of information amongst authorities scattered across disparate spaces. This is far from unproblematic, however, because such procedures are different from those enacted where authorities conduct response individually. Acting alone, emergency services follow a clear, three-tier chain of command that structures the flow of information according to their linear, hierarchical organisation. This chain of command is commonly known as ‘Gold-Silver-Bronze’ (2008). Personnel who belong to bronze command account for on-the-ground responders directly attending the emergency. They exchange information with those located in silver command, who instruct bronze commanders on the tactics to employ in
responding to the emergency. The highest echelon, gold, communicates with the silver tier to direct the overall strategic approach for dealing with the emergency.\(^{17}\)

As a procedure for structuring the flow of information, this internal chain of command contrasts sharply with the multi-agency procedures involving Liaison Officers, RWGs and expert cells described in the last section. Whereas chains of command filter information according to a vertical hierarchy, multi-agency procedures exist as a network that mirrors the spatial and temporal unfolding of the emergency itself. Attempting to adopt the information sharing procedures required for multi-agency response, however, causes authorities severe problems. ‘What always happens’ the emergency planner explained ‘is that people default to speaking to their own organisation’. Faced with a multi-agency incident, responders fall back on internal procedures for information sharing. This causes information to circulate up and down the ranks of individual agencies rather than spreading across all the organisations involved.

When internal chains of command are followed instead of multi-agency arrangements, aspects of the physical, elemental forces constituting emergencies can exceed the information generated to represent them. An example of elemental excess being produced in this way occurred when authorities attended a large fire in the early hours of a summer morning in 2014. Due to the size of the emergency, authorities formed a multi-agency

\(^{17}\)An example from the Fire and Rescue Service’s response to a fire emergency illustrates this chain of command and exchange of information. Bronze level personnel would respond to the fire itself, using resources to control and extinguish the flames. The Silver tier would gain information regarding the fire from the Bronze tier and instruct them concerning the resources to use. Personnel located at the Gold tier would be responsible for communicating with the Silver tier and deciding the broader strategic approach taken. This might include, for instance, what rescue efforts to undertake and the amount of resources that can be dedicated to response (2008).
Response Working Group (RWG). Although multi-agency information sharing procedures were activated, the firefighters who were first to arrive at the scene reported only to their internal seniors rather than across the spectrum of agencies involved. In so doing, plumes of smoke containing high levels of sulphur were able to spread over a large area without the dangers implicit being recognised and dealt with by specialist organisations such as Public Health England and the Environment Agency\(^\text{18}\). Following information sharing procedures internal to single agencies, the physical smoke produced from the fire exceeded the information generated and circulated to represent the emergency.

Although following internal information sharing procedures in events necessitating multi-agency response can cause elemental excess, establishing multiple lines of communication between different agencies can have similar effects. In the last section, I described how the number of sites and cells from which to source and transmit information adapt in a way continually attuned to the emergency’s own physical development. Nevertheless, cases have shown that new gaps in information sharing appear as emergencies become more complex and new information conduits are established. In a snowstorm in 2010, local stockpiles of salt rapidly declined as authorities attempted to clear roads and train tracks. In response, a National Salt Cell was established. One of the Cell’s tasks was to implement a delivery schedule informing responders at different sites about when they should expect the delivery of new salt reserves. From the perspective of the RWG, who were in direct communication with the Salt Cell, ‘There was a lack of reliability of the salt delivery schedule from the National Salt Cell’. In particular, a disparity developed between the time the

\(^{18}\)Debrief Report 29/05/2016
schedule stipulated reserves would be delivered and the time they arrived. Such an inconsistency might seem inconsequential, but its logistical ramifications are wide reaching. Resources for the distribution of salt within a specific site, such as personnel, are prepared according to the delivery schedule. If salt is delivered before specified, the resources to distribute it might not yet be available. If salt is delivered late, resources might have been deployed for another matter. A lack of information regarding the delegation of resources meant that snowfall continued to disrupt transport infrastructure in a way that exceeded the capability of authorities to act.

In line with research discussed earlier (Adey, 2015, Bennett, 2010, Forman, 2017), it needs to be reiterated, however, that elemental forces possess agency beyond their capture and enrolment within the processes to which they contribute. Excess generated due to the recalcitrant agency of the elemental is evident in this case with the capacity that the elements in emergencies have for physically materialising in ways beyond the scope of those trying to generate information representative of them. In particular, such a divergence between the physical capacity of the elements and their capacity to be represented informationally appears where predictions concerning emergencies fail to come to fruition. Returning to the floods of 2014, forecasts generated by those warning mechanisms discussed earlier were surpassed when the emergency that they addressed unravelled. Before the floods, the Met Office’s Weather Warning Service made projections for likely rainfall based on rainfall that had occurred in previous years. As one report into the

19 The report claims further that there was also a lack of transparency around the rationale ‘in determining priorities for deliverables and what the criteria was (for ranking sites in terms of need)’.

20 Strategic debrief 02/04/2010
flood states, however, such projections were dashed when ‘there was twice average rainfall in December to February’ in which months ‘they (referring to responders) experienced 75% of the rainfall they would expect in a year’\textsuperscript{21}.

Weather warnings are not only produced according to probability calculations. Rather, they result from calculations concerning how different elemental forces contained within a meteorological front might combine to produce a collective impact. In the case of the 2014 floods, reports show how elemental forces combined in ways contrasting with that projected by the Weather Warning Service, leading to impacts that diverged from predictions. Rainfall, already beyond calculated average, ‘combined with record spring tides, due to (an) East Coast Surge (meaning that) ground water also reached some of its highest levels’ (ibid). Returning to the scene later, situation reports suggest that the physical unfolding of the emergency further outstripped the information contained in forecasts. Updates circulated across authorities on the 14\textsuperscript{th} February state, for instance, that ‘tidal surge forecast line on the graph was very high, and the previous tide had exceeded the forecast’\textsuperscript{22}.

Where it derives from the unpredictable mutability of the elements, excess may result in procedures directing information sharing resources to the wrong place, meaning information that accurately represents the emergency unravelling cannot be generated.

During the floods of 2014, Liaison Officers had been reporting from areas that weather warning information considered most severely affected. This allowed for the release of

\textsuperscript{21}Situation Report 09/02/2014

\textsuperscript{22}Situation Report 14/02/2014
regular situation reports that, at least temporarily, allowed information circulated to represent the event’s occurrence. However, shifts in the direction of the water, brought about by the introduction of the wind, severely affected authorities’ capability to generate precise, timely information. Returning to one of the reports into the floods: ‘coastal flooding was impacted on by the direction of the wind (which) became south-westerly’\textsuperscript{23}. At this point, accurate information from the sites most effected by the emergency could not be immediately generated and circulated as Liaison Officers had been directed to other sites entirely. Unexpected permutations in the weather mean that information generated in one moment might become unhinged from the physical unfolding of the emergency in the next.

\textit{‘Some Information’s Really Tricky’: The Political Effects of Elemental Excess for Emergency Response}

The lags in information sharing evidenced above, wherein elemental forces physically underpinning emergencies exceed the procedures and technologies designed to generate and circulate information representative of them, have important political ramifications. In his work on emergency governance, Ben Anderson has demonstrated that the ability of authorities to sense, know and name the specific type of emergency attended to is crucially important for engendering an appropriate response (2015, 2017). It is an ability fraught, however, with complications. By obfuscating clear understandings of their unfolding, emergencies reveal themselves as ‘an occasion ... when government is brought into contact with that which is outside it and that which threatens to exceed its capacities’ (Anderson, 2015, 6). Anderson explains how such complications arise where individual responders face

\textsuperscript{23}Situation Report 17/02/2014
unpredictable situations and feel out of their depth trying to make a definitive decision for all authorities involved in response. Complications in naming the emergency derive in Anderson’s account from the paradoxical situation wherein authorities are compelled to act but without knowing comprehensively the event they must act within. Charting a different course from Anderson’s, I outline below how the effects of elemental excess documented in the last section complicates authorities’ ability to generate comprehensive understandings of the emergency attended which, in turn, renders problematic their ability to provide adequate response.

Beyond scuppering attempts to generate and circulate information, elemental excess extends into further practical problems for emergency responders. In particular, excess frustrates attempts by different authorities to consolidate consensual understandings of the emergency. A theme throughout the interview, the emergency planner summarised this issue by stating initially that ‘some information’s really tricky’\textsuperscript{24}. Taking into account the forms of elemental excess which affected information sharing during the 2014 flooding, they expressed doubt regarding the capacity of information to represent what was happening physically on the ground, raising suspicions concerning information along the following lines of inquiry: ‘What’s flooded? How do we know? How reliable is that?’ Overall, the emergency planner summarised, describing how ‘You never know entirely what’s going on and you’ve always got people trying to…translating that information backwards and forwards’\textsuperscript{25}. Uncertainty starts to creep in as elemental excess is recognised to have

\textsuperscript{24}Interview with Emergency Planner 03/02/2017

\textsuperscript{25} Interview with Emergency Planner 03/02/2017
severed the crucial relationship between the emergency’s physical unfolding and its informational representation.

Discord between the physical unfolding of the emergency and its informational representation has implications for authorities’ in terms of accurately labelling the emergency. In accordance with their measurement against a range of standardised criteria, an emergency can be located into different categories of event. Quoting government guidance: ‘the scale of the impact of the event or the situation’ (2013, 11) should be calculated when determining the event confronted, as should ‘the demands it is likely to make of local responders’ (ibid). Furthermore, judgements on the category of event faced should be informed by consideration of whether there is need for ‘the exceptional deployment of resources’ (ibid). A Major Incident is one such category of event that might be declared. A Major Incident refers to ‘an event or situation requiring a response under one or more of the emergency services’ major incident plans’ (2016, 7). In particular, it designates an event whose severity is such that the resources required for response are beyond those possessed by local authorities\(^{26}\). A Major Incident will call forth further resources supplied either by authorities in regions neighbouring the site of the emergency or central government. Politically, the declaration of a Major Incident thus has a heavy bearing on the course of action authorities take to govern emergencies, determining what authorities need to coordinate with one another and the resources made available to them.

---

\(^{26}\)A Major incident is different from a Multi-agency Incident. Both require coordination between responders but a multi-agency incident does not include stipulations regarding the severity of damage that an emergency has caused.
Where the elemental forces physically constituting the emergency exceed the information generated and circulated representing them, past cases suggest that it is not always easy for authorities to reach consensus regarding whether an emergency should be judged a Major Incident. The authorities focused on in this research did not declare the floods they faced in 2014 as a Major Incident. Such was the case despite a report into the flood claiming that ‘There was a feeling that the duration of the flooding, the complexity of the issues faced and the breadth of areas had made it a very significant multi-agency incident and therefore it should have been declared a major incident’ (2014, 18). The same report later reveals that this shortcoming was caused by the effects that elemental excess brought about for information sharing. With procedures and technologies failing to attune to the physical unfolding of the emergency, a comprehensive account of the emergency overall could not be generated, meaning a Major Incident could not be declared because ‘no single organisation felt it met the trigger point for them to call a Major Incident’\(^\text{27}\). By asserting that no single organisation thought it necessary, the explanation offered suggests that, although multi-agency response arrangements were activated and correspondent lines of communication established, multiple perspectives on the emergency, aligned to specific organisations, persisted instead of a view held in consensus. Shown in the previous section to result from elemental excess, these fragmentary perspectives introduced ambiguity regarding the emergency and curtailed authorities’ capability to declare a Major Incident when they should have.

\(^{27}\text{RWG Debrief 24/05/2014}\)
As government guidance was shown to instruct earlier in this section, situating an emergency into a specific category of event is, in political terms, very significant. By labelling an emergency, authorities determine what actions can be taken to govern it. By complicating how an emergency should be categorised, the effects of elemental excess, then, bear the potential to jeopardise authorities’ ability to deploy resources proportionate to the physical force of the emergency. In so doing, elemental excess renders problematic the state’s capacity to meet societal needs in times of emergency.

**Conclusion**

The paper has presented research into the procedures and technologies authorities use to share information during emergencies. Warning systems, cell formation, situation reporting and battle rhythms shape the deployment of devices like cloud-based platforms and telecommunications facilities to generate and circulate information. Relating, for instance, to flood water, smoke produced in fires, the effects of snowfall or broader meteorological conditions preceding an event, the information created and shared represents the elemental forces physically constitutive of the emergency. In turn, this information organises and guides the interventions authorities make to respond to emergencies.

The case itself compels engagement with, and a distinctive contribution to, current geographical debates concerning the entanglement of the elemental in communication infrastructures. Extant literature opened up to consideration how, rather than simply seeking to mitigate the damage they might cause, authorities actually harness the elemental forces physically constitutive of emergencies to enable information sharing. Elemental forces play different roles in facilitating information sharing. Their physical manifestation informs the configuration of information sharing conduits whilst the capacities of elements
are actualised in representative form too, appearing as information transmitted through the
diffuse scenes across which the emergency unfolds. Despite being outlined in other
literature, the practices researched in this paper suggests that these capacities do not exist
separately from one another. Instead, the representative and physical capacities of
elemental forces are mutually cultivated through procedures that spatially and temporally
formalise the deployment of information sharing technologies. In general, geography should
take care when exploring the capacity of the elemental. Beyond outlining the capacities that
elements actualise, closer attention should be afforded to the practices through which
relations are forged between such capacities and the dynamic of mutual cultivation that
organise their actualisation.

I have argued additionally that information sharing in emergencies is important to consider
because it brings into sharp focus how elements might disrupt the information sharing
practices to which they otherwise contribute. Drawing on existing literature (Anderson and
Wiley, 2009), the paper has significantly extended the concept of excess in two ways to
understand how the force of the elemental disrupts information sharing. Following the
argument that capacity is something that hinges on the relations that elements make, the
paper shows first how elemental excess is produced by the way that information sharing
practices are themselves enacted. Thus, excess sometimes emanates from the procedures
and technologies designed to incorporate the elemental into information sharing. The paper
secondly demonstrated how the capacity of elements to manifest themselves and transform
in unforeseeable ways during emergencies disrupts information sharing. Such
transformative capacity complicates authorities’ attempts to attune with the physical
unfolding of emergencies and thus generate information representative of them.
Contributing to debates more generally, excess suggests that a more nuanced treatment is
required when considering the effects of the enrolment of elemental forces into
information sharing. The functioning of information sharing is reliant on the incorporation of
elements into its enactment. Nevertheless, excess indicates that the envelopment of
elemental forces into information sharing is far from seamless. Geography should closely
scrutinise here how information sharing is shaped and conditioned in a way inconveniently
attached to the tension between the elemental as a facilitator, on one hand, and by its
recalcitrance, on the other.

Extending further our understanding of the disruption that elemental forces cause, I have
also detailed how excess translates into broader political complications for authorities in
terms of governing emergencies. Elemental excess makes it difficult for authorities to know
accurately the emergency event to which they are attendant and consequently ensure the
 provision of adequate response arrangements. By extending the concept of excess to
explain this difficulty, the paper reveals that the capacities and roles that the elemental
enacts in information sharing can directly impact the capacities and roles that governments
enact in governing emergencies overall. Taken at a broad register, the paper asserts that the
force of the elemental needs to be considered in terms of its interruptive effects on political
processes, especially where such force bears upon authorities’ own capability to act or not.
